Abstract: This paper is devoted with numerical solution of the system fractional differential equations (FDEs) which are generated by optimization problem using the Chebyshev collocation method. The fractional derivatives are presented in terms of Caputo sense. The application of the proposed method to the generated system of FDEs leads to algebraic system which can be solved by the Newton iteration method. The method introduces a promising tool for solving many systems of non-linear FDEs. Two numerical examples are provided to confirm the accuracy and the effectiveness of the proposed methods. Comparisons with the fractional finite difference method (FDM) and the fourth order Runge-Kutta (RK4) are given.

Keywords: Non-linear programming, penalty function, dynamic system, Caputo fractional derivatives, Chebyshev approximations, finite difference method, Runge-Kutta method.

Nomenclature

\(D^\alpha\): The Caputo fractional derivative of order \(\alpha\);
\(\mathbb{N}\): The set of all nature numbers;
\([\alpha]\): The ceiling function to denote the smallest integer greater than or equal to \(\alpha\);
\(\mathbb{R}\): The set of all real numbers;
\(\nabla h(x)\): The gradient of the function \(h(x)\);
\(\mu\): An auxiliary penalty variable;
\(\theta\): A constant;
\(T_n(x)\): The Chebyshev polynomial of degree \(n\);

1 Introduction

In last decades, fractional calculus has drawn a wide attention from many physicists and mathematicians, because of its interdisciplinary application and physical meaning [1, 2]. Fractional calculus deals with the generalization of differentiation and integration of non-integer order. Fractional differential equations have been the focus of many studies due to their frequent appearance in various applications in fluid mechanics, biology, physics and engineering [3]. Consequently, considerable attention has been given to the solutions of FDEs and integral equations of physical interest. Most FDEs do not have exact analytical solutions, so approximate and numerical techniques [4, 5] must be used. Several numerical methods to solve FDEs have been given such as, homotopy perturbation method [5], homotopy analysis method [6], collocation method [7, 14] and others [12].

Representation of a function in terms of a series expansion using orthogonal polynomials is a fundamental concept in approximation theory and form the basis of the solution of differential equations [15, 16]. Chebyshev polynomials are widely used in numerical computation. One of the advantages of using Chebyshev polynomials as a tool for expansion functions is the good representation of smooth functions by finite Chebyshev expansion provided that the function \(y(x)\) is infinitely differentiable.

The coefficients in Chebyshev expansion approach zero faster than any inverse power in \( n \) as \( n \) goes to infinity.

Optimization theory is aimed to find out the optimal solution of problems which are defined mathematically from a model arise in wide range of scientific and engineering disciplines. Many methods and algorithms have been developed for this purpose since 1940. The penalty function methods are classical methods for solving non-linear programming (NLP) problem [17, 18]. Also, differential equation methods are alternative approaches to find solutions to these problems. In this type of methods the optimization problem is formulated as a system of ordinary differential equations so that the equilibrium point of this system converges to the local minimum of the optimization problem [19, 21].

In this article, we will compare our approximate solution with those numerical obtained using the implicit finite difference method. It has been shown that FDM is a powerful tool for solving various kinds of problems [22, 23]. Also, this technique reduces the problem to a system of algebraic equations. Many authors have pointed out that the FDM can overcome the difficulties arising in the calculation of some numerical methods, such as, finite element method.

The main aim of the presented paper is concerned with the application of the Chebyshev collocation method and fractional finite difference method to obtain the numerical solution of the system of FDEs which is generated from the non-linear programming problems and study the convergence analysis of the proposed method.

The structure of this paper is arranged in the following way: In section 2, we introduce some basic definitions about Caputo fractional derivatives, the definition of the optimization problem and its generated system of FDEs. In section 3, we derive an approximate formula for fractional derivatives using Chebyshev series expansion and estimate an upper bound of the resulting error of the proposed formula. In section 4, numerical examples are given to solve the system of FDEs which obtained from the non-linear programming problem and show the accuracy of the presented methods. Finally, in section 5, the paper ends with a brief conclusion and some remarks.

2 Preliminaries and notations

In this section, the formulation of the optimization problem and its corresponding system of FDEs are given and we present some necessary definitions and mathematical preliminaries of the fractional calculus theory required for our subsequent development.

2.1 The fractional derivative in the Caputo sense

The Caputo fractional derivative operator \( D_\alpha \) of order \( \alpha \) is defined in the following form

\[
D_\alpha f(x) = \frac{1}{\Gamma(m-\alpha)} \int_0^x \frac{f^{(m)}(\xi)}{(x-\xi)^{\alpha-m+1}} d\xi, \quad \alpha > 0,
\]

where \( m-1 < \alpha \leq m, m \in \mathbb{N}, x > 0 \). Similar to integer-order differentiation, Caputo fractional derivative operator is linear

\[
D_\alpha (c_1 p(x) + c_2 q(x)) = c_1 D_\alpha p(x) + c_2 D_\alpha q(x),
\]

where \( c_1 \) and \( c_2 \) are constants. For the Caputo’s derivative we have \( D_\alpha C = 0 \), \( C \) is a constant,

\[
D_\alpha x^n = \begin{cases} 0, & \text{for } n \in \mathbb{N}_0 \text{ and } n < [\alpha]; \\ \frac{\Gamma(n+1)}{\Gamma(n+1-\alpha)} x^{n-\alpha}, & \text{for } n \in \mathbb{N}_0 \text{ and } n \geq [\alpha]. \end{cases}
\]

We use the ceiling function \([\alpha]\) to denote the smallest integer greater than or equal to \( \alpha \) and \( \mathbb{N}_0 = \{0, 1, 2, \ldots\} \). Recall that for \( \alpha \in \mathbb{N} \), the Caputo differential operator coincides with the usual differential operator of integer order.

For more details on fractional derivatives definitions and their properties see ([15], [24]).

2.2 Optimization problem and its corresponding system of FDEs

Consider the non-linear programming problem with equality constraints defined by

\[
\text{minimize } f(x), \quad \text{subject to } x \in M, \tag{3}
\]

with \( M = \{x \in \mathbb{R}^n : h(x) = 0\} \), where \( f : \mathbb{R}^n \to \mathbb{R} \) and \( h = (h_1, h_2, \ldots, h_p)^T : \mathbb{R}^n \to \mathbb{R}^p \) (\( p \leq n \)). It is assumed that the functions in the problem are at least twice continuously differentiable, that a solution exists, and that \( \nabla h(x) \) has full rank. To obtain a solution of (3), the penalty function method solves a sequence of unconstrained optimization problems. A well-known penalty function for this problem is given by

\[
F(x, \mu) = f(x) + \mu \frac{1}{\theta} \sum_{i=1}^p (h_i(x))^\theta, \tag{4}
\]

where \( \theta > 0 \) is a constant and \( \mu > 0 \) is an auxiliary penalty variable. The corresponding unconstrained optimization problem of (3) is defined as follows

\[
\text{minimize } F(x, \mu) \quad \text{s.t. } x \in \mathbb{R}^n. \tag{5}
\]

\[\]

\[\]

\[\]

\[\]

\[\]

\[\]

\[\]
For more details about NLP problem can be found in ([12–14], [17], [18]).

We can write the NLP problem in a system of fractional differential equations as follows: Consider the unconstrained optimization problem (5), an approach based on fractional dynamic system can be described by the following FDEs

\[ D^\alpha x(t) = -\nabla_x F(x, \mu), \quad 0 < \alpha \leq 1, \]  

(6)

with the initial conditions \( x(t_0) = c_i, \quad i = 1, 2, \ldots, n \).

Note that, a point \( x \) is called an equilibrium point of (6) if it satisfies the right hand side of Eq.(6). Also, we can rewrite the fractional dynamic system (6) in more general form as follows

\[ D^\alpha x_i(t) = g_i(t, \mu, x_1, x_2, \ldots, x_n), \quad i = 1, 2, \ldots, n. \]  

(7)

The steady state solution of the non-linear system of FDEs (7) must be coincided with local optimal solution of the NLP problem (3).

### 3 Derivation an approximate formula for fractional derivatives using Chebyshev series expansion

The well known Chebyshev polynomials [25] are defined on the interval \([-1, 1]\) and can be determined with the aid of the following recurrence formula

\[ T_{n+1}(z) = 2zT_n(z) - T_{n-1}(z), \quad T_0(z) = 1, \quad T_1(z) = z, \quad n = 1, 2, \ldots. \]

The analytic form of the Chebyshev polynomials \( T_n(z) \) of degree \( n \) is given by

\[ T_n(z) = n \sum_{i=0}^{\lceil n/2 \rceil} (-1)^i 2^{n-2i-1} \frac{(n-i-1)!}{(i)!((n-2i)!)} z^{n-2i}, \]  

(8)

where \( \lceil n/2 \rceil \) denotes the integer part of \( n/2 \).

The orthogonality condition is

\[ \int_{-1}^{1} T_i(z) T_j(z) \frac{dz}{\sqrt{1-z^2}} = \begin{cases} \pi, & \text{for } i = j = 0; \\ 0, & \text{for } i = j \neq 0; \end{cases} \]

In order to use these polynomials on the interval \([0, L]\) we define the so called shifted Chebyshev polynomials by introducing the change of variable \( z = \frac{2t}{L} - 1 \). The shifted Chebyshev polynomials \( T_n^\alpha(t) \) are defined as

\[ T_n^\alpha(t) = T_n\left(\frac{2t}{L} - 1\right) = T_{2n}\left(\sqrt{t/L}\right). \]

The analytic form of the shifted Chebyshev polynomials \( T_n^\alpha(t) \) of degree \( n \) is given by

\[ T_n^\alpha(t) = n \sum_{k=0}^{n} (-1)^{n-k} 2^{2k} \frac{(n+k-1)!}{L^k(2k)!((n-k)!)} t^k, \quad n = 2, 3, \ldots. \]  

(9)

The function \( x(t) \), which belongs to the space of square integrable functions on \([0, L]\), may be expressed in terms of shifted Chebyshev polynomials as

\[ x(t) = \sum_{i=0}^{\infty} c_i T_i^\alpha(t), \]  

(10)

where the coefficients \( c_i \) are given by (for \( i = 1, 2, \ldots \))

\[ c_i = \frac{2}{\pi} \int_{0}^{L} x(t) T_i^\alpha(t) \, dt. \]  

(11)

In practice, only the first \( (m+1) \)-terms of shifted Chebyshev polynomials are considered. Then we have

\[ x_m(t) = \sum_{i=0}^{m} c_i T_i^\alpha(t). \]  

(12)

**Theorem 3.1** (Chebyshev truncation theorem) [25]

The error in approximating \( x(t) \) by the sum of its first \( m \) terms is bounded by the sum of the absolute values of all the neglected coefficients. If

\[ x_m(t) = \sum_{k=0}^{m} c_k T_k^\alpha(t), \]  

then

\[ E_T(m) \equiv |x(t) - x_m(t)| \leq \sum_{k=m+1}^{\infty} |c_k|, \]  

(14)

for all \( x(t) \), all \( m \), and all \( t \in [-1, 1] \).

The main approximate formula of the fractional derivative of \( x_m(t) \) is given in the following theorem.

**Theorem 3.2** Let \( x(t) \) be approximated by Chebyshev polynomials as (12) and also suppose \( \alpha > 0 \), then

\[ D^\alpha x_m(t) = \sum_{i=0}^{m} \sum_{k=0}^{i} c_i w_{i,k}^{(\alpha)} t^{k-\alpha}, \]  

(15)

where \( w_{i,k}^{(\alpha)} \) is given by

\[ w_{i,k}^{(\alpha)} = (-1)^{i-k} \frac{2^2 i (i+k-1)! \Gamma(k+1)}{L^k(i-k)! (2k)! \Gamma(k+1 - \alpha)}. \]  

(16)

**Proof.** Since the Caputo’s fractional differentiation is a linear operation we have

\[ D^\alpha x_m(t) = \sum_{i=0}^{m} c_i D^\alpha (T_i^\alpha(t)). \]  

(17)

Employing Eqs.(1) and (2) on the formula (9) we have

\[ D^\alpha T_i^\alpha(t) = 0, \quad i = 0, 1, \ldots, \left\lfloor \alpha \right\rfloor - 1, \quad \alpha > 0. \]  

(18)
Also, for \( i = \lceil \alpha \rceil, \lceil \alpha \rceil + 1, \ldots, m \), and by using Eqs.(1) and (2), we get

\[
D^\alpha T_j^*(t) = \sum_{k=\lceil \alpha \rceil}^i \sum_{j=0}^{k-\lceil \alpha \rceil} \Theta_{i,j,k} T_j^*(t),
\]

(20)

where (for \( j = 0, 1, \ldots \))

\[
\Theta_{i,j,k} = \frac{(-1)^{i-k} 2(i+k-1)! \Gamma(k-\alpha+\frac{1}{2})}{h_j \Gamma(k+\frac{1}{2})(i-k)! \Gamma(k-\alpha-1)(k-j-\alpha+1)2^k}.
\]

Proof. We concern the properties of the shifted Chebyshev polynomials [25] and expanding \( t^{k-\alpha} \) in Eq.(19) in the following form

\[
t^{k-\alpha} = \sum_{j=0}^{k-\lceil \alpha \rceil} c_{kj} T_j^*(t),
\]

(21)

where \( c_{kj} \) can be obtained using (11) where \( x(t) = t^{k-\alpha} \) then

\[
c_{kj} = \frac{2}{h_j \pi} \int_0^1 \frac{t^{k-\alpha} T_j^*(t)}{\sqrt{1-t^2}} dt, \quad h_0 = 2, h_j = 1, j = 1, 2, \ldots
\]

At \( j = 0 \) we find

\[
c_{j0} = \frac{1}{\pi} \int_0^1 \frac{t^{k-\alpha} T_j^*(t)}{\sqrt{1-t^2}} dt = \frac{1}{\sqrt{\pi}} \Gamma(k-\alpha+1/2),
\]

also, at any \( j \) and using the formula (9) we can find that

\[
c_{kj} = \frac{1}{\sqrt{\pi}} \sum_{r=0}^{j-1} \frac{(-1)^{j-r} (j+r-1)! 2^{r+1} \Gamma(k+r-\alpha+1/2)}{(r-j)! (2r)! \Gamma(k+r-\alpha+1)L^2},
\]

for \( j = 1, 2, \ldots \). Employing Eqs.(19) and (21) gives

\[
D^\alpha(T_j^*(t)) = \sum_{i=\lceil \alpha \rceil}^{k-\lceil \alpha \rceil} \sum_{j=0}^{k-\lceil \alpha \rceil} \Theta_{i,j,k} T_j^*(t), \quad i = \lceil \alpha \rceil, \lceil \alpha \rceil + 1, \ldots
\]

where

\[
\Theta_{i,j,k} = \begin{cases} 
\frac{(-1)^{i-k} 2(i+k-1)! \Gamma(k-\alpha+\frac{1}{2})}{h_j \Gamma(k+\frac{1}{2})(i-k)! \Gamma(k-\alpha-1)(k-j-\alpha+1)2^k} \sum_{k=\lceil \alpha \rceil}^{i} \sum_{j=0}^{k-\lceil \alpha \rceil} \Theta_{i,j,k} T_j^*(t), & j = 0; \\
\frac{(-1)^{i-k} 2(i+k-1)! \Gamma(k-\alpha+\frac{1}{2})}{h_j \Gamma(k+\frac{1}{2})(i-k)! \Gamma(k-\alpha-1)(k-j-\alpha+1)2^k} \sum_{k=\lceil \alpha \rceil}^{i} \sum_{j=0}^{k-\lceil \alpha \rceil} \Theta_{i,j,k} T_j^*(t), & j = 1, 2, \ldots
\end{cases}
\]

After some lengthy manipulation \( \Theta_{i,j,k} \) can put in the following form (for \( j = 0, 1, \ldots \))

\[
\Theta_{i,j,k} = \frac{(-1)^{i-k} 2(i+k-1)! \Gamma(k-\alpha+\frac{1}{2})}{h_j \Gamma(k+\frac{1}{2})(i-k)! \Gamma(k-\alpha-1)(k-j-\alpha+1)2^k} \sum_{k=\lceil \alpha \rceil}^{i} \sum_{j=0}^{k-\lceil \alpha \rceil} \Theta_{i,j,k} T_j^*(t),
\]

(22)

and this completes the proof of the theorem.

Theorem 3.4 The error \( |E_T(m)| = |D^\alpha x(t) - D^\alpha x_m(t)| \) in approximating \( D^\alpha x(t) \) by \( D^\alpha x_m(t) \) is bounded by

\[
|E_T(m)| \leq \sum_{i=m+1}^{\infty} c_i \left( \sum_{k=\lceil \alpha \rceil}^{i} \sum_{j=0}^{k-\lceil \alpha \rceil} \Theta_{i,j,k} \right).
\]

(23)

Proof. A combination of Eqs.(10), (12) and (20) leads to

\[
|E_T(m)| = \left| D^\alpha x(t) - D^\alpha x_m(t) \right| = \sum_{i=m+1}^{\infty} c_i \left( \sum_{k=\lceil \alpha \rceil}^{i} \sum_{j=0}^{k-\lceil \alpha \rceil} \Theta_{i,j,k} T_j^*(t) \right).
\]

but \( |T_j^*(t)| \leq 1 \), so, we can obtain

\[
|E_T(m)| \leq \sum_{i=m+1}^{\infty} c_i \left( \sum_{k=\lceil \alpha \rceil}^{i} \sum_{j=0}^{k-\lceil \alpha \rceil} \Theta_{i,j,k} \right),
\]

and subtracting the truncated series from the infinite series, bounding each term in the difference, and summing the bounds completes the proof of the theorem.

4 Numerical implementation

In order to illustrate the effectiveness of the proposed method, we implement them to solve the following system of FDEs which is generated from the non-linear programming problem.

4.1 Optimization problem 1:

Consider the following non-linear programming problem

\[
\text{minimize } f(x) = 100(u^2 - v)^2 + (u - 1)^2,
\]

subject to \( h(x) = u(u - 4) - 2v + 12 = 0 \).

The optimal solution is \( x^* = (2, 4) \), where \( x = (u, v) \). For solving the above problem, we convert it to an unconstrained optimization problem with quadratic penalty function (4) for \( \theta = 2 \), then we have \( F(x, \mu) = 100(u^2 - v)^2 + (u - 1)^2 + \frac{1}{2}\mu(u(u - 4) - 2v + 12)^2 \), where \( \mu \in \mathbb{R}^+ \) is an auxiliary penalty variable. The
corresponding non-linear system of FDEs from (6) is
defined as
\[ D^\alpha u(t) = -400(a^2 - r)v(t) - 2(u(t) - 1) - \mu(2u - 4)(a^2 - 4u - 2v + 12), \]
\[ D^\alpha v(t) = 200(u^2 - v) + 2u(a^2 - 4u - 2v + 12), \quad 0 < \alpha \leq 1, \]
with the following initial conditions \( u(0) = 0 \) and \( v(0) = 0 \).

1.I: Implementation of Chebyshev approximation
Consider the system of fractional differential equations (25). In order to use the Chebyshev collocation method, we first approximate \( u(t) \) and \( v(t) \) as
\[ u_m(t) = \sum_{i=0}^{m} a_i T_i^\alpha(t), \quad v_m(t) = \sum_{i=0}^{m} b_i T_i^\alpha(t). \]  
From Eqs.(26) and Theorem 3.2 we have
\[ \sum_{i=0}^{m} \sum_{k=|\alpha|}^{i} a_i T_i^\alpha(t)^k - a = -400\left(\sum_{i=0}^{m} a_i T_i^\alpha(t)^2 - \sum_{i=0}^{m} b_i T_i^\alpha(t)\right)^2 - \sum_{i=0}^{m} b_i T_i^\alpha(t), \]
\[ \left(\sum_{i=0}^{m} a_i T_i^\alpha(t)\right) - 2\left(\sum_{i=0}^{m} a_i T_i^\alpha(t) - 1\right) - \mu\left(2 \sum_{i=0}^{m} a_i T_i^\alpha(t) - 4\right), \]
\[ \left(\sum_{i=0}^{m} a_i T_i^\alpha(t)^2 - 4\sum_{i=0}^{m} a_i T_i^\alpha(t) - 2\sum_{i=0}^{m} b_i T_i^\alpha(t) + 12\right), \]
\[ \sum_{i=0}^{m} \sum_{k=|\alpha|}^{i} b_i T_i^\alpha(t)^k - a = 200\left(\sum_{i=0}^{m} a_i T_i^\alpha(t)^2 - \sum_{i=0}^{m} b_i T_i^\alpha(t)\right)^2 - \sum_{i=0}^{m} b_i T_i^\alpha(t), \]
\[ 2\mu\left(\sum_{i=0}^{m} a_i T_i^\alpha(t)^2 - 4\sum_{i=0}^{m} a_i T_i^\alpha(t) - 2\sum_{i=0}^{m} b_i T_i^\alpha(t) + 12\right). \]
We now collocate Eqs.(27) and (28) at \( (m + 1 - |\alpha|) \) points \( p_0 = 0, 1, \ldots, m + 1 - |\alpha| \) as
\[ \sum_{i=0}^{m} \sum_{k=|\alpha|}^{i} a_i T_i^\alpha(t_p)^k - a = -400\left(\sum_{i=0}^{m} a_i T_i^\alpha(t_p)^2 - \sum_{i=0}^{m} b_i T_i^\alpha(t_p)\right)^2 - \sum_{i=0}^{m} b_i T_i^\alpha(t_p), \]
\[ \left(\sum_{i=0}^{m} a_i T_i^\alpha(t_p)\right) - 2\left(\sum_{i=0}^{m} a_i T_i^\alpha(t_p) - 1\right) - \mu\left(2 \sum_{i=0}^{m} a_i T_i^\alpha(t_p) - 4\right), \]
\[ \left(\sum_{i=0}^{m} a_i T_i^\alpha(t_p)^2 - 4\sum_{i=0}^{m} a_i T_i^\alpha(t_p) - 2\sum_{i=0}^{m} b_i T_i^\alpha(t_p) + 12\right), \]
\[ \sum_{i=0}^{m} \sum_{k=|\alpha|}^{i} b_i T_i^\alpha(t_p)^k - a = 200\left(\sum_{i=0}^{m} a_i T_i^\alpha(t_p)^2 - \sum_{i=0}^{m} b_i T_i^\alpha(t_p)\right)^2 - \sum_{i=0}^{m} b_i T_i^\alpha(t_p), \]
\[ 2\mu\left(\sum_{i=0}^{m} a_i T_i^\alpha(t_p)^2 - 4\sum_{i=0}^{m} a_i T_i^\alpha(t_p) - 2\sum_{i=0}^{m} b_i T_i^\alpha(t_p) + 12\right). \]
For suitable collocation points we use the roots of shifted Chebyshev polynomial \( T_{m+1-|\alpha|}^\alpha(t) \).
Also, by substituting Eq.(26) in the initial conditions \( u(0) = v(0) = 0 \), we can find
\[ \sum_{i=0}^{m} (-1)^i a_i = 0, \quad \sum_{i=0}^{m} (-1)^i b_i = 0. \]
Equations (29) and (30), together the equations of the initial conditions (31), give \( (2m + 2) \) of non-linear algebraic equations which can be solved using the Newton iteration method, for the unknowns \( a_i \) and \( b_i, i = 0, 1, \ldots, m \).

1.II: Implementation of fractional FDM
In this section, the fractional finite difference method with the discrete formula (27), (28) is used to estimate the time \( \alpha \)-order fractional derivative to solve numerically the system of FDEs (25). Using (27), (28) the restriction of the exact solution to the grid points centered at \( x_n = nk, n = 1, 2, \ldots, N \), in Eqs.(25)
\[ \sigma_{\alpha,k} \sum_{j=1}^{n} \omega_j^{(\alpha)}(u_{n-j+1} - u_{n-j}) + O(k) = -400(u_n^2 - v_n)u_n \]
\[ -2(u_n - 1) - \mu(2u_n - 4)(u_n^2 - 4u_n - 2v_n + 12), \]
\[ \sigma_{\alpha,k} \sum_{j=1}^{n} \omega_j^{(\alpha)}(v_{n-j+1} - v_{n-j}) + O(k) \]
\[ = 200(u_n^2 - v_n) + 2\mu(u_n^2 - 4u_n - 2v_n + 12), \]
\[ \sigma_{\alpha,k} \sum_{j=1}^{n} \omega_j^{(\alpha)}(u_{n-j+1} - u_{n-j}) = -400(u_n^2 - v_n)u_n \]
\[ -2(u_n - 1) - \mu(2u_n - 4)(u_n^2 - 4u_n - 2v_n + 12) + TE_1(t), \]
\[ \sigma_{\alpha,k} \sum_{j=1}^{n} \omega_j^{(\alpha)}(v_{n-j+1} - v_{n-j}) = 200(u_n^2 - v_n) \]
\[ + 2\mu(u_n^2 - 4u_n - 2v_n + 12) + TE_2(t), \]
where \( TE_1(t) \) and \( TE_2(t) \) are the truncation terms. Thus, according to Eqs.(34) and (35), the numerical scheme is consistent, first order correct in time. The resulting finite difference equations are defined by
\[ \sigma_{\alpha,k} \sum_{j=1}^{n} \omega_j^{(\alpha)}(u_{n-j+1} - u_{n-j}) = -400(u_n^2 - v_n)u_n \]
\[ -2(u_n - 1) - \mu(2u_n - 4)(u_n^2 - 4u_n - 2v_n + 12), \]
\[ \sigma_{\alpha,k} \sum_{j=1}^{n} \omega_j^{(\alpha)}(v_{n-j+1} - v_{n-j}) = 200(u_n^2 - v_n) \]
\[ + 2\mu(u_n^2 - 4u_n - 2v_n + 12), \quad n = 1, 2, \ldots, N. \]
This scheme presents a non-linear system of algebraic equations. In our calculation, we used the Newton iteration method to solve this system.
In figures 1 and 2, we presented a comparison between the approximate solution \((u(t), v(t))\) using the Chebyshev collocation method with \(m = 4\), numerical solution using the fractional finite difference method with \(k = 0.002\) and the solution using Runge-Kutta method for \(\alpha = 1\) and \(\alpha = 0.85\), respectively. From these figures, we can conclude that the obtained numerical solutions of the proposed methods are in excellent agreement with those obtained from Runge-Kutta method.

**4.2 Optimization problem 2:**

Consider the equality constrained optimization problem [26]

\[
\text{minimize } f(x) = (x_1 - 1)^2 + (x_1 - x_2)^2 + (x_2 - x_3)^2 + (x_3 - x_4)^4 + (x_4 - x_5)^4,
\]

subject to \(h_1(x) = x_1 + x_2^2 + x_3^3 - 2 - 3\sqrt{2} = 0\),

\(h_2(x) = x_2 - x_3^2 + x_4 + 2 - 2\sqrt{2} = 0\),

\(h_3(x) = x_1 x_5 - 2 = 0\).

(38)

The solution of (38) is \(x^* \cong (1.19, 1.362, 1.47, 1.64, 1.68)\) and this is not an exact solution. For solving the above problem, we convert it to an unconstrained optimization problem with quadratic penalty function (4) for \(\theta = 2\), then we have

\[
F(x, \mu) = f(x) + \frac{1}{2} \mu \sum_{\ell=1}^{3} (h_{\ell}(x))^2,
\]

where \(\mu \in \mathbb{R}^+\) is an auxiliary penalty variable. The corresponding non-linear system of FDEs from (6) is defined as

\[
D^\alpha s(t) = -\nabla f(x) - \mu \nabla h(x) h(x), \quad 0 < \alpha \leq 1,
\]

(40)

with the following initial conditions \(x(0) = (2, 2, 2, 2)^T\) that is not feasible.

The obtained numerical results of the problem (40) using the proposed methods are presented in tables 1-5, where in table 1, we presented the numerical solution \(x(t) = (x_1(t), x_2(t), ..., x_5(t))\) using Chebyshev collocation method with \(m = 5\) at \(\alpha = 1\) and in table 2, we presented the numerical solution using the fractional FDM with

</table>

$k = 0.002$ at $\alpha = 1$ and in table 3, we presented the numerical solution using the fourth order Runge-Kutta method. But in tables 4 and 5, we presented the numerical solution of the same system (40) with $\alpha = 0.85$ using the two proposed methods, respectively. From these tables, we can conclude that our solutions of the proposed methods are in excellent agreement with the solution using RK4 method.

5 Conclusion and remarks

In this article, we implemented an efficient numerical method for solving the system of FDEs which is generated from the NLP problem. The fractional derivative is considered in the Caputo sense. The properties of the Chebyshev polynomials are used to reduce the system of fractional differential equations to the solution of system of algebraic equations. It is evident that the overall errors can be made smaller by adding new terms from the series (26). The convergence analysis of the proposed method and derivation an upper bound of the error are introduced. From illustrative examples, it can be seen that the proposed numerical approach can obtain very accurate and satisfactory results. The numerical comparison among the fourth order Runge-Kutta ($\alpha = 1$) and the solution obtained using finite difference method with the proposed methods shows that our technique perform rapid convergence to the optimal solutions of the optimization problems. Also, from the obtained numerical results we can conclude that our results are in excellent agreement with the exact solution and those from the RK4 method. All numerical results are obtained using Matlab.
